

Do weather changes matter?

Marc Los Huertos

August 25, 2016

1 Introduction

According to the the Inter-Governmental Panel on Climate Change or IPCC, the temperature has been changing about 0.X degrees C per 100 years – but this global average is not evenly distributed accross the globe.

How can we appreciate potential changes accross the whole globe? Perhaps, we can begin to appreciate how temperature (and/or rainfall) might be changing on local scales.

Thus, let's begin to understand how do temperature changes "map" onto a community that we care about? In other words, do weather changes matter?

1.1 Goals of this Document

1. Describe the goals and approach for the project;
2. Provide or point to resources to prepare for and conduct the project; and
3. Describe how we will evaluate the project process and products.

2 Project Description

2.1 Driving Question(s)

Projects can often be structured as questions, but sometimes it is worth phrasing the questions in a number of ways – this might help you find ways that you might find the question more provocative and interesting. For example,

- Is my region's climate changing?
- How is climate change affecting my community?

But you can modify these questions to develop the project that you might find compelling.

In addition, we may develop "sub-questions" that can be developed or answered as chunks, which will be used to answer the main question or questions. For example,

- Are there biases in weather data? Can these biases be corrected? If so, how?

- How can we evaluate trends? What are the most appropriate statistical tools to test for trends?
- What is the best way to display visual data? Are there best practices to guide a public product to make it more compelling or interactive?

2.2 Public Product

Science is a social project. From the questions we ask, to the results and their presentation, science is embedded in a culture of norms. Thus, as part of this project, students will produce a narrative blog with the following characteristics:

- Appropriate and thoughtful statistical analysis;
- professionally appearing and interactive graphics; and
- narrative that describes the climate and climate implications for a community.

3 Approach

Students will have the following tools available:

- Servers where stored weather data can be downloaded;
- R Studio Server with some scripts & libraries to help develop analyses;
- Github to store project codes; and
- Shiny app templates that might be used as a container for interactive content.

3.1 Team Membership and Expert Groups

Each of us form an essential component for the effort. Organized as teams and expert groups, we will disassemble the project into chunks that each of us will contribute in specific and effective ways.

For this project, the following students have been assigned to the teams below:

	Member	Team
1	Jon	1
2	Jean	1
3	Gene	2
4	Jorge	2
5	Kim	3
6	Betty	3
7	Fran	3

We will develop expert groups on an ad hoc, as-needed basis.

3.2 Learning Goals

For this project, you will use weather data to the question "do weather changes matter". How you answer the question is largely up to you, however, there are some learning goals associated with this project:

- Ability to download and process weather data;
- quantify temporal trends in weather data;
- evaluate environmental impacts on human or non-human communities; and
- communicate conclusions to the public.

Throughout this project, your team and instructor will develop the strategies and skills to address this question and help you make some conclusions and present the results to the public.

4 Project Stages

1. Decide what makes a good public product;
2. understand how weather data is stored, curated, and evaluated;
3. download and analyze data (i.e. make inferences) to create a public product;
4. search peer reviewed articles to evaluate ecological, economic, and sociological implications of climate patterns; and
5. write blog to describe results.

4.1 Session 1: Components of a Public Product

Team Exercise: As the first component of the project, search for webpages that use data to describe temperature changes on Earth's surface. The Github Wiki has a link to the Collaborative Documents for our project. Document each site you evaluate in Google Doc to evaluate the public product.

As you evaluate the pages to develop a set of standards and criteria that we can use to measure our own success.

Each team will work to develop criteria that we can use to evaluate the public products, which will be further developed to evaluate each public product produced for our project.

To accomplish this, each student will evaluate 2 public products and write a few paragraphs that answer the following questions:

1. What are the goals of the product?
2. Were the goals met?
3. If the goal was met, describe 2-3 ways that this was accomplished. If the goal was not met, describe 2-3 ways that prevented the goal from being met.

Figure 1: Public products require some careful thought – Disaster projects might be range from inaccurate and embarrassing and to useless and offensive (Yikes!). As an example above demonstrates, projects require care to ensure that the product is intellectually compelling and sensitive to a wide range of audiences. This example is Neither! As the instructor, it is my role to provide the resources and guidance to help you develop projects we will be proud to make available to the public.

4. Describe 2 characteristics that seem like important or valuable ways for a public product to be evaluated.
5. Describe how these characteristics were used in the team's product evaluation criteria.

Once these have been developed, the instructor will collate these into a grading structure for our own public product.

Session Evaluation Criteria The contribution will be graded based on the depth and clarity in which the above questions were answered and how these were effectively translated into our product

4.2 Session 2: How is the Earth's Temperature Taken?

How are temperature data collected? This turns out to be a more complicated question than we might imagine at first. Let's begin by discussion what are the potential data quality issues with temperature data? We might begin by thinking about the data in terms of precision and accuracy.

There are three typical measures of temperature associated with the Earth:

- Land-based Temperatures
- Sea-surface Temperatures

- Remotely Sensed Data (e.g. Satellite)

Since we will only be evaluating land-based measurements, please focus on these. For this session, read and summarize the following questions:

1. How is land-based temperature taken?
2. How have these methods changed over time?
3. How are different sources of data combined?
4. What is the geographic range of temperature readings?

Write a paragraph that describes source of bias and inaccuracies in land-based temperature measurements.

4.2.1 Session Evaluation Criteria

These contributions will be evaluated based on completeness, accuracy, and clarity. Once these have been submitted, work with your team members to create a document that can be put into the “Collaborative Documents”.

4.3 Session 3: Where’s [sic] the data!!!

Watch this video

We might need to better appreciate the subtleties of how these data are stored, so we know our conclusions are reasonable. Write a 1-2 paragraph summary that answers the following questions:

1. How as data storage changed in the last 500 years?
2. how data are curated?
3. how are data checked for quality?

Once you have submitted the document, use the Collaborative Documents to describe how weather is stored and made accessible as a team.

4.3.1 Session Evaluation Criteria

These contributions will be evaluated based on completeness, accuracy, and clarity.

4.4 Session 4: Getting Data Effectively

Let’s begin by defining the characteristics of our data acquisition process. As a group please outline a series of criteria that should be used to ensure we can get data for our project. For example, we might consider getting data in reliable way. Or data that is updated regularly (e.g. daily, yearly).

Once you have defined the characteristics of the collecting process, I suggest you follow the next set of steps to acquire and prepare the data for the final product:

Identify Data Sources Each team will research and evaluate various sources of data. Create a Rmd file that describes the each data set, it sources and how it might become usable using open sources of software. Develop scripts to download data (easier) or create a link to a database (preferred).

Pre-process data Once the team has downloaded data, the files will need to be pre-processed to be imported into R and/or post-process to create a useful dataset. Large data set are often compressed using a vareity of protocols (e.g. zip, tar, gz). So, we we often have to "unzip", "untar", or "ungz". Once files are uncompressed, we need to look at the strcture of the files – that might entail figuring how how columns have been separated or if there are long headers that might get in the way of the importing process. We will have to come up with various methods to deal with these data file strutures.

Import data requires a good understanding of the data structure and how a various software programs import data. We will use an open source software program called R.¹ There are many resources to use R, including some handouts I have made. The functions to read files into R, include `read.csv()`, `read.table()`, etc. We will create some tools for us to use to make this process as painless as possible.

Process data Convert missing values to NA, naming variables, reshaping data);

Create a Rmd file that describes the importing process and data fields.

4.4.1 Session Evaluation Criteria

Once the data has been posted, I will run the Rmd file which will be evaluated based on completness, accuracy, and clarity.

4.5 Session 5: Is there a case for Inference and Causation?

Read the introduction to statistics by Artiola, et al. (2004).

- Artiola, J, Pepper, IL, Brusseau, M. 2004. Environmental Monitoring and Characterization. Chapter 3. Environmental Statistics (pp. 30-48).

For this session, we will analyze the data using a number of tools, but largely linear regression (via linear models in R).

¹Excel was not designed to handle large datasets, i.e. over 1 million rows. For most purposes, this might be enough – Many climate science data often exceed the number of observations that business programs like Excel was designed to do. However, even more compelling is that we are trying to create dataset that can be analyzed by anyone use a range of tools that are at our disposal as educated people. As such, I argue that we should be looking to open source. See the pdf on Liberation through Open Source Software.

4.6 Session 6: Creating an Interactive Public Product

Each student will use a data source to create the public product where we can

Analyze data for patterns (e.g. temporal trends); and

Create compelling graphics (easier); or an interactive shiny app (perferred).

4.6.1 Evaluating Narratives

We will evaluate the public product based on the following criteria:

- Team Work Contribution – Did you fulfill the contract? Submit documentation that of your contribution to the team collaboration.
- Public Product
 - Were the analysis methods and results described effectively?
 - Would stakeholders be find the page compelling? (Describe the evidence that might be used to demonstrate this.)
 - How dies this product align with the matrix we developed as a class at the beginning of the semester?
